Sorba vs AI ConneX Feature-Parity Checklist

Purpose

This document maps the capabilities shown in the Sorba no-code reference flow against the current AI ConneX direction discussed in the transcript and the modular ML assembly-line reference. The goal is to separate what AI ConneX already conceptually supports, what is partially aligned, and what belongs to a later roadmap rather than the first cloud-only release. [cite:253][cite:114][cite:243]

Positioning

Sorba is shown as a packaged no-code platform that covers IoT connection, dataset creation, exploratory analysis, project setup, automated model creation, deployment, IO mapping, and runtime monitoring in one integrated product experience.[cite:253] AI ConneX, as discussed so far, is currently narrower: multi-tenant dataset intake, S3-backed storage, agent-assisted dataset preparation, and a phased path toward cloud model build and delivery with an initial focus on regression and anomaly detection.[cite:114]

Capability Matrix

Capability Area	Sorba Reference	AI ConneX Current Direction	Parity Status	Notes
Multi-tenant workspace	Sorba shows workspace-driven user flows and managed navigation across datasets, projects, and models.[cite:253]	AI ConneX is explicitly intended to work across multiple tenants.[cite:114]	Strong match	Multi-tenancy is more explicit in AI ConneX discussions than in the Sorba demo.[cite:114][cite:253]
Dataset intake	Sorba supports CSV, hot data, and manual data as dataset sources.[cite:253]	AI ConneX intends to accept datasets from portal uploads, databases, and fields, then store them in S3.[cite:114]	Strong match	AI ConneX source coverage is conceptually broad enough, but UI details are not yet defined.[cite:114]
Dataset storage	Sorba persists datasets and versions inside its trainer workflow.[cite:253]	AI ConneX discussion explicitly places uploaded datasets into S3.[cite:114]	Strong match	AI ConneX is clearer on the storage backbone; Sorba is clearer on the productized UX.[cite:114][cite:253]
Dataset versioning	Sorba creates named dataset versions such as 1.0.0 and exposes available versions in the UI.[cite:253]	Transcript mentions dataset versioning and tagging as part of the process direction.[cite:114]	Strong match	This should be part of Phase 1 in AI ConneX, not postponed.[cite:114]

Capability Area	Sorba Reference	AI ConneX Current Direction	Parity Status	Notes
Dataset tagging and metadata	Sorba uses tag-based field selection and feature lists throughout the flow.[cite:253]	Transcript references dataset output tagging and management concepts.[cite:114]	Partial match	AI ConneX has the concept, but not yet the concrete metadata model.[cite:114]
EDA / dataset explorer	Sorba provides summary, trend, scatter plot, box plot, histogram, parallel coordinates, correlation, data quality, and data drift views.[cite:253]	The assembly-line document includes an EXPLORE stage with summary stats, missing values, outliers, correlation, and natural-language report generation.[cite:243]	Strong match	Sorba is implementation-rich; AI ConneX has this as a design reference rather than a delivered module.[cite:253][cite:243]
Data quality analysis	Sorba surfaces outliers, bad quality event counts, Pareto views, and threshold-style diagnostics.[cite:253]	AI ConneX discussion prioritizes cleaning, dataset readiness review, and agent-based checking of whether the data is in good shape.[cite:114]	Strong match	This is central to Phase 1 in AI ConneX.[cite:114]
Data drift analysis	Sorba includes a dedicated Data Drift view with per-tag drift scores and statistical tests.[cite:253]	The assembly-line reference includes drift monitoring as part of MONITOR, and AI ConneX has not yet made it a Phase 1 priority.[cite:243][cite:114]	Partial match	Good for later cloud monitoring; not essential for first dataset-prep release.[cite:243][cite:114]
Synthetic features / synthetic tags	Sorba provides “Add Synthetic Tag” and extra-feature configuration during dataset and analysis setup.[cite:253]	The assembly-line reference includes feature engineering modules such as polynomial, interaction, and date features.[cite:243]	Partial match	Conceptually aligned, but AI ConneX has not yet decided the UX or governance around generated features.[cite:243]
Rules engine	Sorba includes advanced rules during dataset/analysis creation.[cite:253]	AI ConneX discussions do not yet define a formal rules engine, only agent-assisted review and process branching.[cite:114]	Gap	This can be deferred until after basic preparation workflows stabilize.[cite:114]
Project abstraction	Sorba creates projects on top of datasets, then analyses under projects.[cite:253]	The assembly-line reference includes project-level workflow metadata, but the transcript focuses more on tasks and stages than formal project entities.[cite:243][cite:114]	Partial match	AI ConneX should likely adopt Project as a first-class object early for governance and UX clarity.[cite:243]

Capability Area	Sorba Reference	AI ConneX Current Direction	Parity Status	Notes
Analysis abstraction	Sorba separates dataset, project, analysis, and model entities.[cite:253]	AI ConneX discussion currently compresses most of this into “process,” “task,” and “algorithm flow.”[cite:114]	Gap	The object model needs to be formalized in AI ConneX architecture docs.[cite:114]
Algorithm family coverage	Sorba exposes Clustering, Classification, Regression, Optimization, Digital Twin, and Forecasting options.[cite:253]	AI ConneX intentionally narrows initial scope to regression and anomaly detection only.[cite:114]	Intentional gap	This is a scope decision, not a deficiency.[cite:114]
Regression support	Sorba includes regression-capable flows and model instances.[cite:253]	Regression is one of the two explicitly approved initial algorithm targets for AI ConneX.[cite:114]	Strong match	High-priority parity target.[cite:114]
Anomaly detection support	The modular ML assembly-line reference explicitly includes anomaly detection as a first-class branch, and Sorba’s product model is broad enough to support multiple algorithm types even though this demo emphasizes optimization.[cite:243][cite:253]	Anomaly detection is the second explicitly approved initial algorithm target for AI ConneX.[cite:114]	Strong match	High-priority parity target, even if not showcased in this Sorba demo path.[cite:114][cite:243]
Optimization workflows	Sorba demo strongly emphasizes optimization and multi-objective optimization analysis.[cite:253]	AI ConneX has not identified optimization as part of the first approved scope.[cite:114]	Gap	Good roadmap item, but should not distract Phase 1 or early Phase 2 execution.[cite:114]
Forecasting workflows	Sorba exposes forecasting as an algorithm type.[cite:253]	Transcript mentions forecasting conceptually in use-case discussion, but initial algorithm commitment remains regression and anomaly detection.[cite:114]	Intentional gap	Can be added later once time-series handling is formalized.[cite:114]
Digital twin workflows	Sorba exposes digital twin as an algorithm type.[cite:253]	Transcript mentions digital twin as a broader future direction, not an immediate build target.[cite:114]	Intentional gap	Clearly future scope.[cite:114]

Capability Area	Sorba Reference	AI ConneX Current Direction	Parity Status	Notes
Automated pipeline search	Sorba training logs show automated testing of multiple preprocessing/model pipelines such as standard scaler, robust scaler, PCA, and MiniKMeans combinations.[cite:253]	AI ConneX currently follows a manual-first model-development approach and wants cloud implementation to reproduce validated manual results.[cite:114]	Gap	Valuable later, but not for the first controlled release.[cite:114]
Data cleansing job pipeline	Sorba training jobs show cleansing and post-processing as explicit background steps.[cite:253]	AI ConneX places cleansing and readiness validation at the center of Phase 1.[cite:114]	Strong match	One of the strongest direct overlaps.[cite:253][cite:114]
Agent-assisted review	Sorba screens show product workflows, but not agentic review or master-agent orchestration.[cite:253]	AI ConneX explicitly wants ML creation support agents and a master agent to supervise flow decisions.[cite:114]	AI ConneX differentiator	This is a strategic distinction rather than a missing feature.[cite:114]
Intelligent routing by dataset type	Sorba appears largely workflow-driven and form-driven in this demo.[cite:253]	AI ConneX discussion indicates common shared steps followed by dataset- and algorithm-specific branching, with adaptive routing in the middle of the flow.[cite:114]	AI ConneX differentiator	This is one of the most important design differences.[cite:114]
Node-by-node workflow canvas	The assembly-line reference proposes a ReactFlow-style workflow canvas with modular nodes.[cite:243]	AI ConneX has discussed the staged flow but not yet committed to visual canvas as the first UI mode.[cite:114]	Partial match	Useful long-term UX layer, but not mandatory for first delivery.[cite:243]
Stage-isolated testing	The assembly-line reference includes testing individual nodes and running full pipelines.[cite:243]	AI ConneX manual-first validation philosophy is compatible with isolated stage testing.[cite:114]	Strong match	Helpful for development workflow and internal QA.[cite:243][cite:114]
Monitoring dashboard	Sorba includes runtime model dashboards, trend views, and post-deployment operational screens.[cite:253]	The assembly-line reference includes MONITOR, but AI ConneX has not made full runtime monitoring a first-phase deliverable.[cite:243][cite:114]	Partial match	Phase 2 or later cloud-operational capability.[cite:243][cite:114]

Capability Area	Sorba Reference	AI ConneX Current Direction	Parity Status	Notes
Tag ranking / feature ranking	Sorba exposes tag ranking as an analysis artifact.[cite:253]	The assembly-line reference includes feature importance views in validation.[cite:243]	Partial match	Should be added when training/evaluation UI matures.[cite:243]
Real-time / hot-data dataset creation	Sorba supports building datasets directly from live measurements over selected time ranges.[cite:253]	AI ConneX transcript discusses datasets from fields and databases, but current focus is still on dataset preparation flow rather than hot-stream UI.[cite:114]	Partial match	Important later if live operational data becomes a major source class.[cite:114]
Deployment wizard	Sorba includes a structured deployment flow with project selection, instance settings, source/destination, model execution, dashboards, and IO mapping.[cite:253]	AI ConneX wants eventual cloud model delivery, but current discussion is still pre-deployment and preparation oriented.[cite:114]	Gap	Phase 2 feature set.
Auto IO mapping	Sorba can auto-match model inputs and outputs to runtime tags and generate missing structure.[cite:253]	AI ConneX cloud-only plan does not yet need IO mapping at this level.[cite:114]	Intentional gap	Not needed until external runtime integration becomes a priority.[cite:114]
Auto-learning / continuous update options	Sorba includes model instance settings for auto-learning and version inclusion behaviors.[cite:253]	AI ConneX discussions defer retraining and customer-specific adaptive agents to a later phase.[cite:114]	Intentional gap	Should remain out of scope for the first release.[cite:114]
No-code product UX	Sorba is clearly a no-code wizard-driven experience.[cite:253]	AI ConneX aims at workflow support but has not yet finalized whether the user experience is no-code, low-code, or expert-guided.[cite:114][cite:243]	Partial match	UI philosophy should be clarified explicitly.

What AI ConneX Should Match Early

The highest-value early parity targets are the ones that directly support the already approved scope: dataset intake, S3-backed storage, dataset versioning, dataset explorer, data quality review, regression support, anomaly-detection support, and a clean project/object model around dataset-to-analysis flow.[cite:114][cite:243][cite:253] These are the capabilities that strengthen the first cloud-only release without forcing AI ConneX to become a full Sorba clone.[cite:114][cite:253]

Early AI ConneX should therefore include:

- Multi-tenant dataset upload and source registration.[cite:114]
- Dataset versioning and metadata tagging.[cite:114][cite:253]
- Explore/EDA pages with summary, outliers, correlation, and quality analysis.[cite:243][cite:253]
- A formal Project and Analysis object model.[cite:243][cite:253]
- Training/evaluation flow for regression and anomaly detection.[cite:114][cite:243]
- Basic monitoring hooks for later Phase 2 expansion.[cite:243]

What Can Wait

Several Sorba capabilities are powerful but should remain later-stage items for AI ConneX: optimization, digital twin, forecasting expansion, auto-pipeline search, deployment wizards, auto-learning, and deep operational dashboards.[cite:253][cite:114] These are useful roadmap items, but adding them too early would dilute the narrower and more disciplined execution plan agreed in the transcript.[cite:114]

Distinctive AI ConneX Advantages

AI ConneX does not need to replicate Sorba literally to be competitive in its intended scope. The transcript introduces two important differentiators: ML creation support agents and adaptive branching where the workflow is shared at the beginning, changes by dataset type in the middle, and becomes specialized near the training branch.[cite:114] Sorba's demo appears stronger in packaged workflow UX, but AI ConneX can differentiate by being more intelligent in dataset preparation, review, and routing rather than only wizard-driven.[cite:253][cite:114]

Recommended Product Framing

The best framing is not "build Sorba again." The better framing is: build a cloud-first AI ConneX platform that matches Sorba on the essential ML workflow surfaces needed for the first release, while differentiating through multi-tenant data preparation, agent-assisted review, and tighter initial scope control around regression and anomaly detection.[cite:253][cite:114][cite:243]
